While doing a study of European population stratification, I came across an older but interesting study of [old testament priests](#) that compares the Levi tribe (where Moses was a member) with the Cohanim tribe (descendants of Moses's brother Aaron who served as priests). The investigators traced patrilineal inheritance since the temple period 3,000 -2,000 years until present, and showed current levites unlike the Cohanim having a heterogeneous origin. The coalescence of Cohanim chromosomes is dated to between Exodus and the destruction of the first temple in 586 BC.

Most current research is dedicated to between species comparisons but unfortunately the wonderful older Y and mtDNA approaches haven't kept pace with the current SNP technology development. There would be many interesting studies possible following the timeline of European history, yea, yea.
